Follow-up: Aggregates

From [CppReference](#): An aggregate is one of the following types:

- array type
- class type (typically, struct or union), that has
 - no private or protected *direct* (since C++17) non-static data members
 - no *user-declared constructors* (until C++11)
 - no *user-provided constructors* (explicitly defaulted or deleted constructors are allowed) (since C++11) (until C++17)
 - no *user-provided, inherited, or explicit constructors* (explicitly defaulted or deleted constructors are allowed) (since C++17) (until C++20)
 - no *user-declared or inherited constructors* (since C++20)
 - no virtual, private, or *protected* (since C++17) base classes
 - no virtual member functions
 - no *default member initializers* (since C++11) (until C++14)

Concepts pushed to Clang master

“Making new friends” idiom by Dan Saks

Wikibooks

The goal is to simplify creation of friend functions for a class template.

```
1 template<typename T>
2 class Foo {
3     T value;
4 public:
5     Foo(const T& t) { value = t; }
6     friend ostream& operator <<(ostream& os, const Foo<T>& b)
7     {
8         return os << b.value;
9     }
10 };
```

A hidden gem: `inner_product`

4

This makes me so incredibly happy! I literally just yesterday googled, C++17 / C++20 zip to see if they had anything, because I wrote some code in both C++ and [Python](#) and Python was so much more beautiful.

```
int solve(int h, vector<int> w, vector<int> l) {  
    int p = 0;  
    for (int i = 0; i < w.size(); ++i)  
        p = max(p, w[i] - l[i] / 4);  
    return max(0, p - h);  
}  
  
def solve(h, w, l):  
    p = max(a - b//4 for a, b in zip(w, l))  
    return max(0, p - h)
```

Also, I just discovered `std::inner_product` – a beautiful temporary solution to a lack of `zip`.
[#cpp](#) [#inner_product](#)

```
int solve(int h, vector<int> w, vector<int> l) {  
    return max(0, inner_product(begin(w), end(w), begin(l), 0,  
        [](auto a, auto b) { return max(a, b); },  
        [](auto a, auto b) { return a - b / 4; }) - h);  
}
```

Rereading "The Design and Evolution of C++"

= 0

syntax was used for pure virtual function in order to avoid having to add a new keyword such as pure or abstract because the feature was added close to the next release.

13.2.3 Syntax

The curious `=0` syntax was chosen over the obvious alternative of introducing a keyword `pure` or `abstract` because at the time I saw no chance of getting a new keyword accepted. Had I suggested `pure`, Release 2.0 would have shipped without abstract classes. Given a choice between a nicer syntax and abstract classes, I chose abstract classes. Rather than risking delay and incurring the certain fights over `pure`, I used the traditional C and C++ convention of using 0 to represent “not there.” The `=0` syntax fits with my view that a function body is the initializer for a function and also with the (simplistic, but usually adequate) view of the set of virtual functions being implemented as a vector of function pointers (§3.5.1). In fact, `=0` is not best implemented by putting a 0 in the `vtbl`. My implementation places a pointer to a function called `__pure_virtual_called` in the `vtbl`; this function can then be defined to give a reasonable run-time error.

I chose a mechanism for specifying individual functions `pure` rather than a way of declaring a complete class `abstract` because the pure virtual function notion is more flexible. I value the ability to define a class in stages; that is, I find it useful to define some virtual functions and leave the definition of the rest to further derived classes.

- Herb Sutter

Oscar Godson:

One of the best programming skills you can have is knowing when to walk away for a while.
